# Wear os applications

What apps are on wear os. Meilleures applications wear os. What apps are available on wear os. Best wear os applications. List of wear os apps. What apps can you get on wear os. Les meilleures applications wear os.

If you have a great app, wear OS and Google Play can help you take it to users. While the Android apps can send basic notifications to wear OS devices, you can go much further. Extend your apps to support custom wear operating systems and offer a refined and additive user experience in all devices in the wear operating system. If your Apps meet the quality guidelines of the main apps on Android devices and provide a high quality experience for operating system wear devices, your apps have emerged on Google Play for easy discovery. To start, review this page to learn how to distribute OS wear apps to users via Google Play. Make sure you read the Quality of the ESS wear for usability information and quality standards that your apps should meet. When your app is ready, you can choose the designation as an OS wear app from the game console. How to participate in Google Play allows you to perform detectable OS wear apps for wearable users. You can develop and publish using your existing game console account and current distribution and price settings. It is easy to participate - the following sections outline the process. 1. Understanding the guidelines and requirements to prepare a successful launch on the wear operating system, starting by reviewing the guidelines for creating large app experiences with wear. Watch the guidelines for the design developer designer of operating systems for ideas to extend your app to wear the operating system and details on design and outability. While starting to design your OS wear experience, make sure you read and understand the quality criteria for the operating system wear apps. Only the apps that can be used based on the wear system will be designated as an OS wear app on Google Play - your apps can participate if they meet a set of basic quality criteria. See the quality of the app for operating system wear for details. 2. Develop a fantastic operating system wear app when you read guidelines, the next step is to develop your app. The following sections describe how to start building a great experience of app for wear. Design First Wear OS aims to provide users with the right information at the right time. Great experiences of the operating system of wear are hooked and require zero or interaction by minimal user. All Android apps can send basic notifications to wear wearables of the operating system without changes. However, the large apps built for operating system wear are perfect to offer a polished and high quality experience, work on different screen layouts, it works for users with clocks combined with iPhones and deliver a set of convincing functionality to Users. While considering your OS wear app, review the guidelines for the documentation and usability of developers and plans to use them in the maximum possible measure. Packaging of your app If you have an existing app for phones and other devices, we advise you to deliver your app for the clock using the same package name and store the list. This allows users to upgrade to your operating system experience perfectly and allows you to take advantage of reviews and votes you have earned in your app for phones. Package The OS wear app as a separate APK or Android bundle app so that it can be delivered efficiently to your users. This helps bring your app to wear users of the iPhone operating system. To know the packaging of your apps, see Package and distribute operating system wear apps. Test on a variety of devices in à c verify\_remote\_example\_wear\_app For more information, see advertising features. Detection of the app and opening a URL from a clock The Watch app can detect if a user's Companion phone has your app by phone: use the capacity functionality to check if the phone app is installed on the phone Associate. For more information, see the sample on github. If the phone app is not installed on the phone, use the phoneDeviceType.getphonesDeviceType () method to check the type of phone. If phoneDeviceType.device\_type\_android is returned, the phone is an Android phone. Call remoteActivityHelper.StartTremoteTivity () on the operating system wear device to open the App Store on the phone. Use the market uri for your telephones app (which could be different from your phone URI). For example, use a market uri such as: market://details? ID = com.example.android.weak.wear.findevices se phoneDeviceType.device\_type\_ios is returned, it means that the phone is a iOS phone (without gaming stores available). Open the App Store on the iPhone by calling RemoteActivityHelper.StartTremoteActivity () on the wear device. You can specify the iTunes URL of the app, for example, . On an iPhone, from the wear operating system, it is not possible to determine at the code level if the phone app is installed. As a better practice, provide a user mechanism (for example, a button) to manually activate the opening of the App Store. Note that using the RemoteActivityHelper API described above, you can specify that any URL is open on the phone from the watch and no telephone app is required. Details To detect the type of coupled phone Here is a snippet that uses the GetPhoneDeviceType () method to check the type of phone that is coupled by the phone type: var phoneDeviceType: int = phoneDeviceType.getphonesDeviceType (context) int phoneDeviceType = phoneDeviceType. GetPhoneDeviceType (context); The value returned by the GetPhoneDeviceType () method is one of the following: App detection starting from an Android phone the Android phone is in To detect if the user wear devices have your app for the watch: using the Nodeclient, find all the watches connected to the user's phone. For more information, see the sample on github. Using the client capacity, check which of the user's watches installed your app. If your app is not installed on all user watches (compare the results from step 1 with the results from step 2), allow the user to open the playback archive on the devices of the remaining wear operating system from Telephone via remoteactivityhelper.startremoteTivity () method. Specifically, use the market URI for wear wear App (which could be different from the phone app. For example, use a market uri such as: market://details? ID = com.example.android.weable.wear.findevices Localization data for clocks combined with iPhones for clocks combined with iPhone, developers should use the fuse location supplier (FLP) to get data on the location on a clock. See Detecting the position on the wear operating system. If the companion's phone is available, FLP uses the Companion phone for location data. Get only the necessary data in general when you get data from the Internet, you need to get only the necessary data. Otherwise, you can introduce unnecessary latency, use of memory and battery use. When a watch is connected to a Bluetooth LE connection, your app may have access to a bandwidth of only 4 kilobytes per second, depending on the clock. Therefore, the following steps are recommended: Audit Your Network Requests and Answers for Extra Data which is only for a large image Shrink phone application before sending them on a network to a watch for cases where it is A high bandwidth network is required. -Bandwidth Access to the network. Additional code samples The executed diversifyREMOTEPS further demonstrates the use of the APIs covered by this page. page.
